24 **Abstract**

25           Phytopsanitary/quarantine regulations for many countries require that certain dried fruit be  
26 disinfected prior to export; however, current technologies involve the use of toxic chemicals and  
27 conventional thermal methods are not effective causing loss of volatile components, browning  
28 and texture change. Newer physical methods including dielectric heating have been considered,  
29 but information on dielectric properties of dried fruits is lacking. Because the loss factor of insect  
30 pests, Indian meal moth (*Plodia interpunctella*) and navel orangeworm (*Amyelois transitella*), is  
31 several times (26 to 36) greater than that of dried fruits, RF treatment in particular has great  
32 potential for insect disinfection. In this study, the dielectric properties of raisins, dates, apricots,  
33 figs, and prunes with water contents of 15 to 30.2g/100g, were determined between 10-1800MHz  
34 over a range of 20-60°C. The dielectric constant and loss factor of all samples decreased with  
35 increasing frequency, but increased with increasing temperature at each frequency. The loss  
36 factor of all samples increased with increasing water contents/water activity (0.5 to 0.7). The  
37 penetration depths (dps) of RF energy in all samples decreased with increasing frequency and  
38 temperature. The deep dp (28.4-103.7cm) at 27MHz indicates the potential for developing  
39 continuous and large-scale RF treatments for postharvest insect control in dried fruits.

## 42 1. Introduction

43 Dried fruits are important ingredients in several food formulations, such as breakfast  
44 cereals, snack bars, bakery and dairy products. They can be good sources of dietary fiber, various  
45 vitamins including pantothenic acid, and minerals (USDA, 2011). The greatest volume of dried  
46 fruit in the United States is in the Central Valley of California with more than 460,000 metric  
47 tons of raisins (*Vitis vinifera*), dates (*Phoenix dactylifer*), apricots (*Prunus armeniaca*), figs  
48 (*Ficus carica*), and dried plums (*Prunus domestica*) being produced yearly with a value of more  
49 than \$600 million (USDA-NASS, 2009). In 2008, the United States, Turkey, and China were the  
50 top three producers of raisins constituting about 73% of the world's production. The United  
51 States, Chile, France, and Argentina were the top four producers of prunes, with about 83% of  
52 the world's production. Turkey produced the majority of the world's production of dried apricots  
53 (more than 80%), much of this imported and resold as Product of Turkey. Dates and dried figs  
54 were produced mainly in Middle Eastern and Mediterranean countries with, more than 6,860,000  
55 and 819,000 metric tons, respectively, in 2008, accounting for about 96% and 76% of the world  
56 production (FAO, 2008).

57 One of the main problems in production, storage, marketing and exporting of dried fruits  
58 is the loss caused by insect infestation. The Indian meal moth (*Plodia interpunctella*) and navel  
59 orangeworm (*Amyelois transitella*) are two of the most serious postharvest pests of dried fruits  
60 (Simmons & Nelson, 1975; Johnson, Yahia, & Brandl, 2009). Fumigation using methyl bromide  
61 (MeBr) has been a common practice for insect control in the past (Barreveld, 1993), but its use  
62 is being phased out globally under the Montreal Protocol (USEPA, 2001) and alternative,  
63 preferably non-chemical, treatments for postharvest disinfestation of dried fruits are needed.

64 Radio frequency (RF) and microwave (MW) heating (also referred to as dielectric  
 65 heating) have been investigated for insect control in foods (Fu, 2008). In contrast to chemical  
 66 treatment methods, dielectric heating leaves no chemical residues on products, provides  
 67 acceptable product quality and has minimal adverse effects on the environment (Wang, Tang,  
 68 Johnson, Mitcham, Hansen, Hallman, Drake, & Wang, 2003). Compared to conventional  
 69 heating, dielectric heating has a more rapid come-up time to the target temperature due to the  
 70 phenomenon of volumetric heating (Wang, Birla, Tang, & Hansen, 2006). RF consists of  
 71 electromagnetic waves from 3 kHz to 300 MHz, and MW between 300 MHz and 300 GHz  
 72 (Ramaswamy & Tang, 2008). The U.S. Federal Communications Commission (FCC) has  
 73 allocated specific frequencies for industrial, medical, and scientific applications, including 13.56,  
 74 27.12, and 40.68 MHz for RF and 915 and 2450 MHz for MW (Wang & Tang, 2001). Major  
 75 factors affecting dielectric properties of agricultural and biological materials include frequency,  
 76 temperature, salt content, water content, the state of water (frozen, free or bound), and food  
 77 composition (e.g. fat content). In general, the higher the water content, the higher the values of  
 78 dielectric properties of a material (Nelson, 1978; Rynnänen, 1995; Tang, 2005).

79 Dielectric properties of a material consist of dielectric constant ( $\epsilon'$ ) and dielectric loss  
 80 factor ( $\epsilon''$ ) which can be described by the complex relative permittivity  $\epsilon^*$  (Metaxas & Meredith,  
 81 1993):

$$82 \quad \epsilon^* = \epsilon' - j\epsilon'' \quad (1)$$

83 where  $j = (-1)^{0.5}$ ;  $\epsilon'$ , the real component, is a measure of the ability of the material to store  
 84 electromagnetic energy; and  $\epsilon''$ , the imaginary component, is a measure of the ability to dissipate  
 85 electrical energy into heat.

86 For rapid dielectric heating when heat transfer is negligible, temperature rise due to the  
 87 interaction between the dielectric material and the electrical field can be calculated using the  
 88 following equation (Nelson, 1996):

$$89 \quad \rho C_p \frac{\Delta T}{\Delta t} = 5.563 \times 10^{-11} f E^2 \varepsilon'' \quad (2)$$

90 where  $\rho$  is the density of the material in  $\text{kg/m}^3$ ;  $C_p$  is the specific heat of the material in  $\text{J/kg} \cdot ^\circ\text{C}$ ;  
 91  $\Delta T$  is the temperature rise in the material in  $^\circ\text{C}$ ;  $\Delta t$  is the time duration in s,  $f$  is the frequency in  
 92 Hz, and  $E$  is the electric field intensity in  $\text{V/m}$ .

93 Knowledge of dielectric properties is essential to gain a better understanding of the  
 94 heating behavior of the treated materials when subjected to RF or MW fields and for the design  
 95 and development of continuous systems. Dielectric property data for several agricultural  
 96 commodities have been reported, including fresh fruits (Venkatesh & Raghavan, 2004; Wang,  
 97 Monzon, Gazit, Tang, Mitcham, & Armstrong, 2005; Sosa-Morales, Tiwari, Wang, Tang,  
 98 García, & López-Malo, 2009); vegetables (Sıpañoğlu & Barringer, 2003; Venkatesh &  
 99 Raghavan, 2004); and dry foods (Berbert, Queiroz, Sousa, Molina, Melo, & Faroni, 2001;  
 100 Sacilik, Tarimci, & Colak, 2006; Guo, Wang, Tiwari, Johnson, & Tang, 2010;). Dielectric  
 101 property data are also available for several important insect pests, including rice weevils  
 102 (*Sitophilus oryzae*) (Nelson & Charity, 1972), potato beetles (*Leptinotarsa decemlineata*)  
 103 (Colpitts, Pelletier, & Cogswell, 1992), woodworms (Andreuccetti, Bini, Ignesti, Gambetta, &  
 104 Olmi, 1994), codling moths (*Cydia pomonella*) (Tang, Ikediala, Wang, Hansen, & Cavalieri,  
 105 2000; Wang, Tang, Johnson, Mitcham, Hansen, Hallman, Drake, & Wang, 2003; Ikediala,  
 106 Hansen, Tang, Drake, & Wang, 2002), Indian meal moths (*Plodia interpunctella*), navel  
 107 orangeworms (*Amyelois transitella*), Mexican fruit flies (*Anastrepha ludens*) (Wang, Tang,  
 108 Johnson, Mitcham, Hansen, Hallman, Drake, & Wang, 2003), Mediterranean fruit flies (*Ceratitis*

109 *capitata*) (Wang, Monzon, Gazit, Tang, Mitcham, & Armstrong, 2005), and, recently, cowpea  
110 weevils (*Callosobruchus maculatus*) (Jiao, Johnson, Tang, Tiwari, & Wang, 2011) and chestnut  
111 weevils (*Curculio elephas*) (Guo, Wu, Zhu, & Wang, 2011).

112         Knowing the dielectric properties of insects and their host materials are important for  
113 evaluating the potential of RF or MW differential heating. Insects have much higher water  
114 content than dry fruit, thus it is possible that the insects will absorb more RF or MW energy than  
115 the host materials and reach a higher temperature than for the surrounding food providing a  
116 means of killing them with minimal damage to food quality (Wang, Tang, Cavalieri, & Davies,  
117 2003). Differential heating has been evaluated for control of different insects for various  
118 agricultural products as an alternative to chemical fumigation (Tang, Ikediala, Wang, Hansen, &  
119 Cavalieri, 2000; Wang, Tang, Cavalieri, & Davies, 2003; Jiao, Johnson, Tang, Tiwari, & Wang,  
120 2011). The most promising frequency for selective heating of insects in a dried food appears to  
121 be between 10 MHz and 100 MHz. Nelson and Charity (1972) investigated the dielectric  
122 properties of hard red winter wheat (*Triticum aestivum*) and rice weevils (*Sitophilus oryzae*) and  
123 suggested the possibility of differential heating at a low frequency region. Nelson and Stetson  
124 (1974) achieved complete mortality of rice weevil (*Sitophilus oryzae*) infested wheat with much  
125 lower energy at 39 MHz than at 2.45 GHz. In recent years, Wang, Tang, Cavalieri, & Davies  
126 (2003) provided a theoretical basis and experimental model for destruction of codling moth  
127 (*Cydia pomonella*) larvae by preferential heating in dry nuts at 27 MHz. Guo, Wu, Zhu, &  
128 Wang (2011) concluded that dielectric heating below 100 MHz has potential for control of the  
129 chestnut weevil (*Curculio elephas*) in chestnut (*Castanea mollissima*).

130         Information on the dielectric properties of dried fruits such as raisins, dates, apricots, figs,  
131 and prunes over a temperature between 20 and 60 °C is not available in the literature and would

132 be very helpful for developing postharvest insect control using RF and MW energy. The  
133 objectives of this study were: (1) to determine the dielectric properties of five important dried  
134 fruits (raisins, dates, apricots, figs and prunes) at their storage water content and then compare  
135 them with published dielectric properties of two common insect pests in dried fruits; (2) to  
136 determine the effects of frequency (10–1800 MHz), temperature (20–60 °C) , and water content,  
137 on these properties; and (3) to calculate the penetration depth of electromagnetic energy into  
138 these five fruits at 27, 40, 915 and 1800 MHz as a function of temperature.

139

## 140 **2. Material and methods**

### 141 *2.1 Materials and sample preparation*

142 The following foods were evaluated: Thompson seedless raisins (*Vitis vinifera*)  
143 (Caruthers Raisin Packing, Caruthers, CA), Deglet Nour dates (*Phoenix dactylifera*) (Sundate,  
144 Coachella, CA), Turkish apricots (*Prunus armeniaca*) (Specialty Commodities, Los Angeles,  
145 CA), Black Mission figs (*Ficus carica*) (Valley Fig, Fresno, CA), and d'Agen prunes (*Prunus*  
146 *domestica*) (Stapleton Spence Packing, San Jose, CA). These materials were selected to represent  
147 a water content range of 15.0 to 30.2g/100g, which covers the range of specifications in the  
148 applicable United States Standards for Grades of Dried Fruits (U.S. Standards) (USDA, 2004).  
149 Samples were stored under refrigeration (5 °C) until tested. An electric blender was used to grind  
150 the fruit flesh into a paste. Dried fruits were held at room temperature to reach equilibrium  
151 before testing. Values for the dielectric properties of the fifth-instar larvae of Indian meal moths  
152 (*Plodia interpunctella*) and navel orangeworms (*Amyelois transitella*) (10–1800 MHz; 20–60 °C)  
153 were obtained from Wang, Tang, Johnson, Mitcham, Hansen, Hallman, Drake, & Wang (2003).

154 In another experiment, the water contents of raisins, dates, apricots, and figs samples  
155 were raised to 30.2% by adding appropriate amounts of de-ionized water to match that of prunes  
156 to evaluate the effect of total sugar content on dielectric properties. Samples were kept in  
157 covered desiccators at room temperature for 3–5 days for moisture to equilibrate. After two more  
158 days, each sample was mixed, sealed in plastic bags and allowed to equilibrate at room  
159 temperature. The samples were removed and water content was obtained to ensure that all  
160 samples had reached the targeted level of 30.2%.

161

## 162 *2.2 Measurements of chemical components, water content, water activity, and particle density*

163 Fruit chemical components, including ash, total sugars, fat, protein, and vitamin C, were  
164 analyzed by Columbia Food Laboratories, Inc., Corbett, OR, USA using the standard methods.  
165 The initial water content of the dried fruits was determined using the vacuum oven method by  
166 drying a known weight of sample in a vacuum oven (ADP-31, Yamato Scientific America, Inc.,  
167 USA) at  $70 \pm 1$  °C under a pressure of about 100 mm Hg for 6 h (AOAC 934.06, 2000). The  
168 AquaLab water activity meter (Series 3, Decagon Devices, Inc., Pullman, WA, USA) with an  
169 accuracy of  $\pm 0.003 a_w$  was used to measure the water activity of the tested dried fruits at room  
170 temperature. The meter was calibrated using 0.5M KCl ( $a_w$  0.98 at 25 °C) (Decagon, 2009). The  
171 particle density of samples was determined at room temperature using the liquid displacement  
172 method with toluene ( $C_7H_8$ ). Toluene was used due to its low tendency to immerse into the  
173 sample, stable specific gravity and viscosity, and ability to flow smoothly over the sample  
174 surface (Moshenin, 1986). Sample density was calculated by dividing the weight of randomly  
175 selected 25 g by the volume occupied by those samples in 100 ml pycnometers. Three replicates  
176 were used for the calculation of the means and standard divisions. Table 1 lists the chemical

177 components of the tested dried fruits along with their initial water contents, water activities, and  
178 particle density. Water content, water activity, and particle density ranged from 15.0 to  
179 30.2g/100g, 0.5 to 0.7, and 1227.1 to 1422, respectively. Raisins had the lowest water content  
180 (15 g/100g w.b.), water activity (0.5), and particle density (1227.1 kg/m<sup>3</sup>) with prunes having the  
181 largest water content (30.2 g/100g w.b.), water activity (0.7), and particle density (1422.0  
182 kg/m<sup>3</sup>). Total sugars, obtained by chromatographic method, were 71.6, 66.9, 41.8, 51.6, and 35.1  
183 g/100g for raisins, dates, apricots, figs, and prunes, respectively. Comparable data can be found  
184 for these materials at USDA (2011).

185

### 186 *2.3 Dielectric properties measurement system*

187 Dielectric properties of raisins, dates, apricots, figs and prunes were measured at 20, 30,  
188 40, 50, and 60°C, which covers the range relevant to thermal treatments for controlling insects in  
189 agricultural commodities, over a frequency range from 10 to 1800 MHz using the open-ended  
190 coaxial probe technique (Fig. 1). A coaxial probe was connected to an impedance analyzer  
191 (Model 4291B, Innovative Measurement Solutions Inc., Santa Clara, CA, USA). About 25 g of  
192 the sample was filled in a stainless steel test cell (20 mm inner diameter and 94 mm height) to  
193 keep the sample at the given water content and temperature during the measurements. A water  
194 bath (Model 1157, VWR Scientific Products, Niles, IL, USA) containing a 10% water and 90%  
195 ethylene glycol solution was used to control the sample temperature by circulating the solution  
196 (15 l/min) into the jacket of the test cell. A type T thermocouple (0.8 mm diameter and 0.8 s  
197 response time) was used to monitor the sample center temperature.

198

### 199 *2.4 Measurement procedure*

200 The impedance analyzer was first calibrated with open air, a short (a metal block to  
 201 provide a short to the coaxial tip), a 50  $\Omega$  load, and a low-loss capacitor following prescribed  
 202 standard procedure (Wang, Tang, Cavalieri, & Davies, 2003). The coaxial probe was further  
 203 calibrated with a standard air-short-triple de-ionized water calibration procedure. Prior to and  
 204 after each measurement, the probe and the test cell were cleaned with de-ionized water and dried  
 205 with dry air. The sample confined within the test cell was compressed with spring at the base to  
 206 ensure a close contact between the tip of the coaxial probe and the sample during measurements.  
 207 Dielectric properties of each sample were measured at 200 discrete frequencies between 10 and  
 208 1800 MHz at 20, 30, 40, 50 and 60 °C. Mean values and standard deviations of dielectric  
 209 property data were calculated from two replicates.

210

### 211 2.5 Penetration depth

212 Penetration depth ( $d_p$ ) is used to quantitatively describe how MW and RF power interact  
 213 with the food and is defined as the distance in meters where the power is decreased to 1/e  
 214 ( $e=2.718$ ) of the power passing the surface. It can be calculated by the following equation (Von  
 215 Hippel, 1954):

$$216 \quad d_p = \frac{c}{2\pi f \sqrt{2\epsilon' \left[ \sqrt{1 + \left( \frac{\epsilon''}{\epsilon'} \right)^2} - 1 \right]}} \quad (3)$$

217 where  $c$  is the speed of light in free space ( $3 \times 10^8$  m/s). This parameter is important in the  
 218 selection of the appropriate thickness of a material bed to ensure uniform heating and complete  
 219 disinfection of insects during RF or MW processes. Mean values and standard deviations of  
 220 penetration depths were calculated from two replicates of the measured dielectric properties of  
 221 samples.

222

223 **3. Results and analyses**224 *3.1 Frequency-dependent dielectric property*

225 A summary of dielectric properties for the dried fruits is provided in Table 2 and a  
226 graphic depiction of dielectric constants and the loss factors at 20 °C is shown in Fig. 2. The  
227 dielectric properties for these five dried fruits demonstrated a similar trend: they decreased with  
228 increasing frequency. However, differences in the values of dielectric properties of the tested  
229 samples at specific frequencies and temperatures were observed. Prunes had the highest  
230 dielectric constant and loss factor values among the five fruits, followed by figs, apricots, dates  
231 and raisins, respectively; this would be expected since prunes had the highest moisture content.  
232 When frequency increased from 27 to 1800 MHz, the dielectric constant of raisins, dates,  
233 apricots, figs, and prunes at 20 °C decreased linearly from 21.9 to 4.6, 27.2 to 9.8, 33.9 to 17.6,  
234 37.7 to 19.1, and 40.6 to 22; the loss factor decreased from 8.1 to 3.1, 9.0 to 5.1, 14.4 to 8, 11.8  
235 to 6.3, and 17.2 to 10, respectively.

236 In the RF and MW frequency regions, ionic conduction and dipole rotation are the main  
237 mechanisms that cause heating in food materials. Thus, the frequency dependence of the  
238 dielectric properties arises from the frequency dependence of these two mechanisms.  
239 Furthermore, the dielectric properties of materials are dominated by free and bound water  
240 dispersions and ionic conduction within a broad frequency range (Feng, Tang, & Cavalieri,  
241 2002). The dielectric loss factors of dates, apricots, figs, and prunes which have water contents  
242 higher than that of raisins, had negative linear relationship with  $\log f$  when plotted in a semi-log  
243 plot (Fig. 3), especially at high temperatures in the low frequency range (<100 MHz). This  
244 negative linear relationship is caused by the dominant ionic contribution and is common in

245 intermediate ( $a_w = 0.6\text{--}0.9$ ) and high water content foods ( $a_w = 0.95\text{--}0.99$ ) (Venkatesh &  
246 Raghavan, 2004; Sosa-Morales, Tiwari, Wang, Tang, García, & López-Malo, 2009). However,  
247 in raisins, which have a low water content of 15 g/100g, this trend became less evident due to the  
248 poor availability of water molecules to interact with the applied electromagnetic field. Similar  
249 observations have been reported for various dry products such as grains (Nelson, 1987),  
250 sunflower seeds (Sacilik, Tarimci, & Colak, 2006), and legume flour (Guo, Wang, Tiwari,  
251 Johnson, & Tang, 2010).

252

### 253 *3.2 Temperature-dependent dielectric properties*

254 Mean values of the dielectric constant and the loss factor of all tested dried fruits as a  
255 function of temperature at 27, 40, 915, and 1800 MHz are shown in Table 2. The dielectric  
256 properties of all the tested dried fruits increased with increasing temperature from 20 to 60 °C at  
257 each frequency tested. Raisins had the smallest values of dielectric constants (4.6 to 11.5) and the  
258 loss factors (3.1 to 6.5) at 1800 MHz among the measured samples when increasing temperature  
259 from 20 to 60 °C. These values are comparable to the dielectric constants (6 to 13) and the loss  
260 factors (2 to 6) of grapes at 2450 MHz and at the same range of temperature and water content as  
261 obtained by Tulasidas, Raghavan, van de Voort, & Girard (1995). Prunes had the highest values  
262 of dielectric constant (40.6 to 48.9) and loss factor (17.2 to 47.8) between 20 and 60 °C and at 27  
263 MHz. In food with low water content, most of the water in the food system is chemically  
264 associated with other molecules, reducing its response to alternating electromagnetic fields  
265 compared to solvent water. Increasing the temperature to 60 °C, the viscosity was reduced and  
266 the mobility of water molecules increased, and this resulted in an increase in loss factor (Tang,  
267 2005).

268 Fig. 4 shows an example of the dielectric constants and loss factors of navel orangeworm  
269 larvae and prunes as a function of temperature over the measured frequency range between 10  
270 and 1800 MHz. In general, the dielectric properties of navel orangeworm larvae were larger than  
271 that of prunes, especially at the low frequencies (<100 MHz). This may be due to the main ionic  
272 dispersion at low frequencies, as stated previously. The dielectric constants of navel orangeworm  
273 larvae and prunes increased from about 80.2 to 99.4 and from 40.6 to 48.9 at 27 MHz when  
274 temperature increased from 20 to 60 °C, respectively. The dielectric loss factors of navel  
275 orangeworm larvae and prunes increased from 307.8 to 562.7 and from 17.2 to 47.8 at 27 MHz  
276 when temperature increased from 20 to 60 °C, respectively. In the MW region (*e.g.* 915 MHz),  
277 the dielectric loss factor of navel orangeworm larvae and prunes increased slightly from 16.1 to  
278 24.0 and from 10.8 to 11.3 when the temperature increased from 20 to 60 °C, respectively. The  
279 large difference of dielectric loss factors between insects and the tested dried fruits at RF  
280 frequencies (<100 MHz) should lead to a high degree of preferential heating of insects compared  
281 to MW frequencies, although it may be possible to develop MW treatments for preferential  
282 heating if these can be tightly controlled to avoid quality loss to the fruit from overheating.

283

### 284 *3.3 Water content-dependent dielectric properties for dried fruits*

285 The water content of dried fruits is relatively low; however, the effect of a small change  
286 in water content has a significant impact on the dielectric properties of these foods. Fig. 5  
287 illustrates the effect of water content (among different fruits) on the dielectric properties of dried  
288 fruits from 20 to 60 °C and 27 MHz. Both dielectric constants and dielectric loss factors  
289 increased linearly with increasing water content, from 15 g/100g (raisins) to 30.2 g/100g (prunes)  
290 at all tested temperature and frequencies. At temperature 20 °C and frequency 27 MHz, the

291 dielectric constants and loss factors increased from 21.9 to 40.6 and from 8.1 to 17.2 when water  
292 content increased from 15 g/100g to 30.2 g/100g, respectively. Similar trends were observed at  
293 other tested frequencies (data not shown). The higher the water content, the larger was the  
294 dielectric constant and loss factor. Table 3 shows predictive equations for the dielectric constant  
295 and the loss factor as a function of water content at 27MHz.  $R^2$  values ranged from 0.94 to 0.99.  
296 Earlier studies on high ( $a_w = 0.95-0.99$ ) or low ( $a_w = 0.40-0.60$ ) water content foods have found a  
297 similar effect of water content on the dielectric properties of food products including corn  
298 (Nelson, 1978); grapes (Tulasidas, Raghavan, van de Voort, & Girard, 1995); apples (Feng,  
299 Tang, & Cavaliere, 2002); and legume flour (Guo, Wang, Tiwari, Johnson, & Tang, 2010), but  
300 there is little reported data for intermediate ( $a_w = 0.60-0.90$ ) or low ( $a_w = 0.40-0.60$ ) water  
301 content foods having a high sugar content. Sugar and starch have different water binding  
302 properties (Datta, Sumnu, & Raghavan, 2005), so it would be expected that sugar containing  
303 foods would exhibit greater changes in dielectric properties with temperature or frequency than  
304 high starch foods such as legume flour from earlier studies.

305 Fig 6. Shows the dielectric properties of dried fruits at a constant water content of 30.2  
306 g/100g and 20 °C as a function of frequency. When increasing water content of raisins, dates,  
307 apricots, and figs from their initial values to 30.2 g/100g, the dielectric properties had  
308 comparable values as that of prunes. The standard deviations of the  $\epsilon'$  and  $\epsilon''$  for all tested sample  
309 were  $\pm 0.79$ , 0.74, 0.70, 0.75 and  $\pm 0.64$ , 0.58, 0.60, 0.50 at 27, 40, 915, 1800 MHz, respectively.  
310 This indicates that although the total sugars content vary on these dried fruits, 62.2, 60.5, 39.6,  
311 50.2, and 35.1 g/100g for raisins, dates, apricots, figs, prunes, respectively, at the same water  
312 content, their dielectric properties did not differ significantly. Sugar molecules are relatively  
313 large, uncharged, and thus do not interact well with the electromagnetic energy in the tested

314 frequency range. Several earlier studies on fruits such as honeydew melons (Guo, Nelson,  
315 Trabelsi & Kays, 2007) and honey (Guo, Liu, Zhu, & Wang, 2011) showed that sugar reduced  
316 the value of the dielectric properties. Increased ash content reduces the value of dielectric  
317 constant and raised the value of loss factor. The decrease in dielectric constant with the addition  
318 of ash content is due to binding of water in the system which reduces the availability of water for  
319 polarization. However, addition of ash content increases the loss factor due to the fact that ash is  
320 a conductive charge carrier that increases the charged particles in the system and therefore  
321 charge migration is increased (Datta, Sumnu, & Raghavan, 2005). Ahmed, Prabhu, Raghavan, &  
322 Ngadi (2007) measured the dielectric properties of seven Indian honey samples and showed that  
323 when samples have similar water content and different ash content (even though small  
324 difference), their dielectric properties exhibit significantly difference. Raisins, dates, and figs  
325 have lower ash content (1.4–1.9 g/100g) and higher total sugars content (62.2–50.2 g/100g),  
326 while apricots and prunes have higher ash content (4.6 and 3.9 g/100g, respectively) and lower  
327 total sugars content (39.6 and 35.1 g/100g, respectively). These different combinations in  
328 compositions might balance the effect of the total sugars content on the dielectric properties.  
329 Thus, water content plays the dominant role in determining the dielectric properties of the dried  
330 fruits more than other components.

331

### 332 *3.4 Comparing the dielectric properties of dried fruits and insects*

333 The dielectric constant and loss factor for Indian meal moths were clearly greater than  
334 those of raisins, particularly in the RF range (<100 MHz) (Fig. 7). The dielectric constants of  
335 Indian meal moths and raisins at 20 °C ranged from about 81.3 to 69.1 and from 21.9 to 20.2,  
336 respectively, when frequency increased from 27 to 40 MHz. The loss factors for Indian meal

337 moths and raisins at 20 °C ranged from about 210.9 to 149 and from 8.1 to 7.4, respectively,  
338 when frequency increased from 27 to 40 MHz. On the other hand, the dielectric constants and  
339 loss factors of Indian meal moths and raisins were close at the MW range (>100 MHz), which  
340 would likely minimize the possibility for using differential heating to kill insects above 100  
341 MHz. Increasing frequency from 915 to 1800 MHz resulted in further reduction of the dielectric  
342 constants of Indian meal moths and raisins at 20 °C from 39.9 to 37.5 and from 7.8 to 4.6,  
343 respectively. The loss factors of Indian meal moths and raisins from 915 to 1800 MHz at 20 °C  
344 changed from 13.4 to 10.6 and from 3.8 to 3.1, respectively.

345 A similar trend as observed in Fig. 7. for Indian meal moths and raisins is also shown in  
346 Fig. 8 for the dielectric properties of Navel orangeworm and prunes. The dielectric constant  
347 (80.2 to 68.6) and loss factor (307.8 to 12.6) of navel orangeworm larvae were almost double  
348 those of prunes (40.6 to 38.7 for dielectric constant and 17.2 to 15.7 for loss factor) in the RF  
349 range (27 to 40 MHz) at 20 °C. Navel orangeworm is a highly heat tolerant insect (Johnson,  
350 Valero, Wang, & Tang, 2004), and prunes had the highest dielectric properties among the dried  
351 fruits considered in this study.

352 As shown in Eqn. 2, the larger the dielectric loss factor, the larger the generation of  
353 thermal energy at a given frequency. Therefore, Indian meal moth larvae and navel orangeworms  
354 are likely to absorb more energy than dried fruits at frequencies in the RF range, and this could  
355 provide a practical alternative to chemical disinfection.

356

### 357 *3.5 Penetration depth*

358 Penetration depths calculated from the measured dielectric properties of five dried fruits  
359 are summarized in Table 4 for four frequencies over five temperatures at the initial water

360 contents of those samples. The penetration depths of all tested dried fruits decreased with  
361 increasing frequency and temperature. The penetration depth in prunes was the lowest among the  
362 five dried fruits; in raisins the penetration depth was the largest under the same conditions. The  
363 penetration depth of raisins ranged from 103.7 to 91.3 cm when the temperature increased from  
364 20 to 60 °C at 27 MHz. In contrast, the penetration depth of prunes ranged from 66.9 to 28.4 cm  
365 when the temperature increased from 20 to 60 °C at 27 MHz. The penetration depths for the  
366 dried fruits at the MW region were smaller than those at the RF region. For apricots, when the  
367 frequency increased from 27 MHz to 1800 MHz, the penetration depth decreased from 88.8 to  
368 1.8 cm at 20 °C. These results suggest that dried fruits could be treated in large containers and  
369 thick layers of 30 cm or greater in the RF system due to the deeper penetration; however, smaller  
370 containers and thinner layers of product would need to be used in MW treatments to achieve  
371 uniform heating in dried fruits. Deep penetration depths at 27 MHz hold the potential to develop  
372 large-scale industrial RF treatments for postharvest insect control in dried fruits with acceptable  
373 heating uniformity.

374

#### 375 **4. Conclusions**

376 Dielectric properties of raisins, dates, apricots, figs, and prunes at different frequencies  
377 (10–1800 MHz), temperatures (20–60 °C) were measured by an impedance analyzer. Differential  
378 heating for postharvest insect pest control is possible since the dielectric constant and loss factor  
379 of the tested dried fruits is lower than for common insect pests, particularly at RF frequencies.  
380 The dielectric constants and loss factors of the five dried fruits and insects decreased with  
381 increasing frequency and increased with increasing temperature. Lower water content raisins had  
382 the lowest values of dielectric properties, while the higher water content prunes had the highest.  
383 The penetration depth of all dried fruits decreased with increasing frequency and temperature,

384 but is on the order of tens of centimeters, making the development of industrial treatment  
385 systems or disinfection possible, particularly at RF frequencies (*e.g.* 27 MHz).

**Research Highlights**

- Permittivity of dried fruits decreased with increasing frequency.
- Permittivity of dried fruits increased with increasing moisture and temperature.
- Moisture affects the dielectric properties of samples more than other components.
- Differential heating between insects and samples is possible at RF range.
- Penetration depths of samples decreased with increasing frequency or temperature.
